Physician safety is patient safety: Good surgical ergonomics to optimize patient care

Daniel L. Wohl, MD and Theresa Hubbard, DPT for the PSQI Committee

Physicians selflessly provide care to their patients over the course of a 30 to 40-year career. Ideally, we stay healthy and rarely get sick or suffer a serious injury. However, we are not immune from physical infirmity and—like a professional athlete—simply often choose to “play through the pain.” We function in a stressful environment and need to be mindful of how the physical demands of our stressful profession impact our ability to provide optimal care for our patients. Establishing and maintaining consistent proper physical ergonomic movements and body positioning is required to avoid developing career-limiting physical ailments. The practice of otolaryngology-head and neck surgery requires us to repetitively position our bodies to obtain optimal visual and physical access when examining and operating upon patients. This translates to numerous instances where we might lean and strain the lower back, overly hang our heads on flexed necks, or twist something just a bit more, and wind up struggling and sore.1, 2, 3, 4, 5

During a long surgical case, it is easy to display poor posture, commonly with forward head and shoulders with excessive leaning and hunched back (Figure 1). Postural impairments like these often lead to musculoskeletal complaints. Good posture involves maintaining the natural curvatures of the spine: an inward curve in the low back and neck joined by an outward curve in the thoracic spine. Adjusting table height is one way to avoid poor posture and maintain these natural curves. The table should be at a height where the top of the patient is at waist level to the surgical team. We are all different shapes and sizes, so individuals should sit, stand, or stand on a platform in order to achieve correct positioning next to the table. If using video monitors, eyes should be in line with the top edge of the monitor, allowing 15-20 degrees of flexion when looking at the center of the screen.6

With consideration to the lower body, weight should be evenly distributed through both legs (Figure 2). Prolonged shifting of weight to one leg leads to an asymmetrical stance and increases strain on the pelvis and lumbar spine. Instead, rest one foot on a small step stool to decrease pressure and fatigue in the back and legs without assuming an asymmetrical position. Foot pedal position can lead to an asymmetrical stance if not considered carefully. Foot pedals should be placed near the foot and aligned in the same direction as instruments and toward the target quadrant of the patient. If standing on a platform, the foot pedal should also be on the platform. Foot pedals with built-in foot rests are more ergonomic because the foot isn’t moving back and forth as frequently or being actively held above the pedal when it is not in use. Varying which foot uses the pedal throughout cases will help decrease muscle imbalances that occur with repetitive movements.

Switching to a seated position and readjusting the table height also alleviates fatigue from standing. While seated, hips and knees should both be flexed to 90 degrees. Feet should be placed on the floor or a platform to...
Sidney J. Starkman, MD, traveled to Corozal Town, Belize, on a reconstructive surgery mission trip spearheaded by Devinder S. Mangat, MD, with Horizon Community Church and Partners for Belize. The region has only one plastic surgeon, so many patients with congenital and acquired defects had gone untreated prior to the conception of this mission trip. Dr. Starkman’s team was able to perform 54 surgeries.

Facial reconstructive surgery in Belize

Figure 3. Top: Microscope height placed too low and with downward angled eyepieces, requires the surgeon to flex the neck. Bottom: Eyepieces oriented with only slight declination allows the surgeon to operate with the head in a more upright neutral neck position.
